

5

may be a set of one or more processors, or may be a multi-processor core, depending on the particular implementation. Further, processor unit **204** may be implemented using one or more heterogeneous processor systems in which a main processor is present with secondary processors on a single chip. As another illustrative example, processor unit **204** may be a symmetric multi-processor system containing multiple processors of the same type.

Memory **206** and persistent storage **208** are examples of storage devices. A storage device is any piece of hardware that is capable of storing information either on a temporary basis and/or a permanent basis. Memory **206**, in these examples, may be, for example, a random access memory or any other suitable volatile or non-volatile storage device. Persistent storage **208** may take various forms depending on the particular implementation. For example, persistent storage **208** may contain one or more components or devices. For example, persistent storage **208** may be a hard drive, a flash memory, a rewritable optical disk, a rewritable magnetic tape, or some combination of the above. The media used by persistent storage **208** also may be removable. For example, a removable hard drive may be used for persistent storage **208**.

Communications unit **210**, in these examples, provides for communications with other data processing systems or devices. In these examples, communications unit **210** is a network interface card. Communications unit **210** may provide communications through the use of either or both physical and wireless communications links.

Input/output unit **212** allows for input and output of data with other devices that may be connected to data processing system **200**. For example, input/output unit **212** may provide a connection for user input through a keyboard and mouse. Further, input/output unit **212** may send output to a printer. Display **214** provides a mechanism to display information to a user.

Instructions for the operating system and applications or programs are located on persistent storage **208**. These instructions may be loaded into memory **206** for execution by processor unit **204**. The processes of the different embodiments may be performed by processor unit **204** using computer implemented instructions, which may be located in a memory, such as memory **206**. These instructions are referred to as program code, computer-usable program code, or computer-readable program code that may be read and executed by a processor in processor unit **204**. The program code in the different embodiments may be embodied on different physical or tangible computer-readable media, such as memory **206** or persistent storage **208**.

Program code **216** is located in a functional form on computer-readable media **218** that is selectively removable and may be loaded onto, or transferred to, data processing system **200** for execution by processor unit **204**. Program code **216** and computer-readable media **218** form computer program product **220** in these examples. In one example, computer-readable media **218** may be in a tangible form, such as, for example, an optical or magnetic disc that is inserted or placed into a drive or other device that is part of persistent storage **208** for transfer onto a storage device, such as a hard drive that is part of persistent storage **208**. In a tangible form, computer-readable media **218** also may take the form of a persistent storage, such as a hard drive, a thumb drive, or a flash memory that is connected to data processing system **200**. The tangible form of computer-readable media **218** is also referred to as computer recordable storage media. In some instances, computer readable media **218** may not be removable.

Alternatively, program code **216** may be transferred to data processing system **200** from computer-readable media **218**

6

through a communications link to communications unit **210** and/or through a connection to input/output unit **212**. The communications link and/or the connection may be physical or wireless in the illustrative examples. The computer-readable media also may take the form of non-tangible media, such as communications links or wireless transmissions containing the program code.

The different components illustrated for data processing system **200** are not meant to provide architectural limitations to the manner in which different embodiments may be implemented. The different illustrative embodiments may be implemented in a data processing system including components in addition to, or in place of, those illustrated for data processing system **200**. Other components shown in FIG. **2** can be varied from the illustrative examples shown. As one example, a storage device in data processing system **200** is any hardware apparatus that may store data. Memory **206**, persistent storage **208**, and computer-readable media **218** are examples of storage devices in a tangible form.

In another example, a bus system may be used to implement communications fabric **202** and may be comprised of one or more buses, such as a system bus or an input/output bus. Of course, the bus system may be implemented using any suitable type of architecture that provides for a transfer of data between different components or devices attached to the bus system. Additionally, a communications unit may include one or more devices used to transmit and receive data, such as a modem or a network adapter. Further, a memory may be, for example, memory **206** or a cache such as found in an interface and memory controller hub that may be present in communications fabric **202**.

With reference to FIG. **3**, a block diagram of components of a privilege manager in accordance with illustrative embodiments is shown. A portion of system **200** of FIG. **2** is shown with a number of components within privilege manager **302**, all within memory **206** of system **200** of FIG. **2**.

Privilege manager **302** is comprised of components including roles **304**, privilege templates **306**, transform utility **308** and editor **310**. Privilege manager **302** provides a convenient package of services for managing authorization policies using the definitions of roles **304** and privilege templates **306**. Transform utility **308** manages the transition from the platform independent form of definitions in roles **304** and privilege templates **306** into platform specific forms suitable for use on the target platforms. Editor **310** provides a capability to create and modify the source definitions of roles **304** and privilege templates **306**. The source form of the definitions may be stored text or non-text, proprietary or non-proprietary form including storage in a database management system, extensible markup language (XML), or extensible access control markup language (XACML) form of maintaining the policy representation.

The source definitions provided in roles **304** and privilege templates **306** provide a very low-level, granular capability to define, and thus manage, the specification and conveyance of privileges to users or components.

With reference to FIG. **4**, a block diagram of a role-based privilege management system is shown, in accordance with illustrative embodiments. Role-based privilege management system **400** comprises a number of components including an editor **402**, privilege templates **404**, roles **406**, transform utility **408**, target environments **410**, transformation request **412**, and a set of role-based privileges **414**. In various embodiments, privilege templates **404**, roles **406**, and target environments **410** may each refer to a set of elements within. For example, roles **406** comprises a set of roles containing one or more members of the set, the members being specific to the
